

So sánh về product concept trong SaaS Billing industry giữa Vexere vs Stripe, Zoho Billing, Hubspot, Salesforce

Glossary

Vexere	Definition	Implementation status	Stripe	Zoho	HubSpot	Salesforce
Feature / Entitlement	A product capability or usage right that a customer can access after subscription activation, such as CRM access, API access, advanced reports, or a usage/seat limit.	Not implemented as a real entitlement object yet. Current UI has entitlement demo/mock rows only; product/rate plan can approximate entitlement-bearing lines, but there is no dedicated entitlement schema/service/lifecycle.	Feature. Features are linked to Products, Products have Prices, Prices are added as Subscription items, and the customer gains active entitlements from the subscribed Products. Sources: Entitlements, subscriptions overview .	None as a dedicated entitlement object. Closest concepts are plan feature set and addons as optional features /services. Sources: Plans overview, addons overview .	None as a dedicated entitlement object. Closest concepts are product library items and line items used on commerce /subscription records. Sources: use line items, create subscriptions .	None as a standalone entitlement object in CPQ/Billing. Closest concepts are subscription products, bundles, product options, and quote/order lines. Sources: Subscription Products in Salesforce CPQ, Product Bundles in Salesforce CPQ .
Product bundle / combo	The implementation concept for Vexere commercial packages such as SMB or Enterprise. A combo is modeled as a Product whose rate plans represent the sellable package variants. Included products/features/entitlements are attached to the combo product or combo rate plan. Pricing and billing cadence live on the combo's selected rate plan/price, so one package can have distinct monthly, quarterly, half-yearly, and yearly variants without reintroducing subscription-level cadence. This better supports Job 8 than a separate subscription plan tier object, because the same package needs package-level price and cadence while cadence is already governed at rate plan/price level.	Partially implemented and now the intended direction. Schema/code exists for <code>products.product_is_combo</code> and <code>combo_rate_plan_products</code> ; product create/edit supports combo flag, included products, rate plan pricing, and cadence variants. Still needs full entitlement behavior, customer-facing compare/select flow, and migration away from old plan-tier UX where needed.	No native bundle object with child products and a separate combo price. Closest implementation is Product + Price variants, or a multi-product subscription when separate items should remain visible. Source: products and prices, mixed interval subscriptions .	Partial. Product /Plan/Addons can approximate package composition; package-level cadence and price are closest to Plan configuration with associated Addons. Sources: products overview, plans overview, understanding addons .	Approximate with product library items and recurring line items. HubSpot tracks recurring line items on subscription records and splits records when billing terms differ, rather than modeling a rich bundle object. Source: create subscriptions .	Product Bundle in Salesforce CPQ: parent product with product options /features, where option pricing can be included or separate. Source: Product Bundles in Salesforce CPQ .
Subscription plan tier	A business-facing label for a commercial package such as SMB or Enterprise, not a separate implementation object. In Vexere implementation, approximate each plan tier as a Product bundle / combo and define its package price and billing cadence through combo rate plan / price variants. Avoid implementing a standalone <code>subscription_plan_tier</code> object as the source of truth because it would duplicate product/rate-plan concepts and make Job 8 harder; package-level monthly/yearly pricing must follow the cadence that already lives on rate plan/price, not on the subscription.	Deprecated as implementation direction. Old/current code still contains <code>subscription_plan_tiers</code> , <code>subscription_plan_tier_items</code> , service, routes, and UI drawer, but Glossary direction is to stop treating this as source of truth and use Product combo instead. Keep only as business language or remove/refactor implementation later.	Product + Price setup; entitlements can be mapped from Products /features. Sources: products and prices, entitlements .	Product + Plan, with associated Addons and default subscription values. Sources: products overview, plans overview, addons overview .	Product library item or recurring product configuration used to create subscription line items. Sources: create and manage products, create subscriptions .	Subscription Product or Product Bundle in Salesforce CPQ, configured through Products, Price Books, and Product Options before being used on Quote Lines. Sources: Subscription Products in Salesforce CPQ, Product Bundles in Salesforce CPQ .
Subscription	A customer-specific subscription instance for one customer / SaaS customer. It is the contract container for phases, item versions, collection method, status, and billing/payment lifecycle. Billing cadence should come from selected rate plans/prices inside subscription item versions, not from a loose subscription-level cadence override.	Partially implemented. CRUD/list UI and API exist for Subscriptions with company, status, collection method, billing anchor/timing, start/end date, next bill date, and <code>SubscriptionItems</code> . Missing real phase model, item version history, scheduled changes, and full lifecycle/payment automation.	Subscription. Sources: subscriptions overview, billing cycle .	Subscription. Source: create and manage subscriptions .	Subscription record created from recurring line items, payment links, quotes, or invoices. Source: create subscriptions .	Subscription / contract lifecycle record, typically originating from Quote and Order flow in CPQ/Billing. Sources: Subscription Products in Salesforce CPQ, Amend Your Contracts and Assets .
Subscription item	A billable or entitlement-bearing line inside a subscription phase, such as a combo package, add-on, usage-based fee, or one-time charge. In the phase model, the concrete item state is a subscription item version: selected product/rate plan/price variant, quantity, price override if any, and billing-relevant configuration for that phase. For package/tier sales, the subscription item should usually point to the combo product's rate plan variant rather than to a separate subscription plan tier object.	Partially implemented. Subscription Items are created from subscription CRUD and reference <code>rate_plan_id</code> , quantity, status, and pricing overrides. Missing phase-owned item versions, historical price snapshots on the subscription side, future item changes, and entitlement activation behavior.	Subscription item with Price and optional quantity; in Subscription Schedules, phase items define prices active during a phase. Sources: subscriptions overview, subscription schedules .	Subscribed Plan /Addons on a Subscription, including customer-specific overrides. Sources: create and manage subscriptions, addons overview .	Subscription line item; line items are product /custom entries specific to a subscription or commerce record. Sources: use line items, create subscriptions .	Quote Line / Order Product for a subscription product, carrying quantity, pricing, term, and billing attributes. Sources: Subscription Products in Salesforce CPQ, Invoicing Recurring Products .
Subscription phase	A versioned commercial configuration for a subscription over an explicit date range. A phase contains the subscription item versions active during that period. Related concepts: current phase, next /scheduled phase, phase boundary, free trial phase, pending item changes, and staged pricing such as year-1/year-2 terms. Phases belong to the subscription, must not overlap, and should only have intentional gaps such as pause/cancel/no-active-billing periods. Current scope only needs active phase plus optional next phase, while the data model should allow multiple future phases later.	Not implemented. No dedicated phase table/model/API/UI was found. Current subscription has direct start/end/billing fields and current <code>SubscriptionItems</code> , so it can represent only a flat current configuration, not current/next phases, scheduled changes, overlap validation, or phase-owned item versions.	Subscription Schedule phase. Stripe phases define different subscription configurations over time, including future price/item changes and trial-to-paid flows. Source: subscription schedules .	Future-dated subscriptions, scheduled plan changes, trial periods, plan /addon changes, and subscription-specific overrides approximate parts of this behavior, but Zoho does not expose the same public phase object. Source: create and manage subscriptions .	No direct phase object in standard subscriptions; subscription edits and recurring line-item changes cover some cases. HubSpot is less explicit about a phase timeline model. Source: create subscriptions .	Amendment, renewal, quote line groups, contract terms, and dated quote/contract line behavior can approximate staged commercial terms. Salesforce CPQ does not use Stripe-like schedule phases as the primary public term. Sources: Amend Your Contracts and Assets, Subscription Terms, CPQ quote date evaluation .

Billing cycle	The generated service period for invoice/payment-request calculation. A billing cycle is derived from the active subscription phase, the subscription item version's selected rate plan/price, and that rate plan's billing interval/cadence. For combo packages, the combo rate plan/price defines the package cadence and package price. Related concepts: billing interval/cadence, billing period /invoice period, mixed-cadence subscription, price basis, converted billing-period unit price, and proration. If multiple items in one subscription have different cadences, invoice generation should split items into coherent billing-period groups. If a phase boundary creates a partial period, long-term handling is normal proration; current scope avoids automatic proration by applying normal changes from the next billing period.	Partially implemented. Rate plan/price has <code>billing_interval</code> and <code>billing_interval_count</code> ; invoice simulation writes <code>billing_invoices</code> and <code>billing_invoice_lines</code> with period start/end and converts amounts by billing interval. Missing production scheduler, mixed-cadence invoice grouping, phase-derived periods, automatic proration, and full payment-request generation.	Stripe billing periods depend on the recurring interval of the Price and the billing cycle anchor. Stripe supports multiple prices and prorations; interval changes and mixed subscriptions require careful anchor /proration handling. Sources: billing cycle , mixed interval subscriptions , prorations .	Zoho uses billing cycles/frequencies on subscriptions /plans/addons, supports prorated invoices/credit notes, and can bill usage/addons by cycle. Changing billing frequency can affect the billing date. Sources: create and manage subscriptions , proration , creating addons .	HubSpot subscriptions bill recurring line items by billing frequency and can prorate upgrades or added/increased line items. HubSpot tends to align added line items to subscription frequency, which is less flexible than Vexere's intended item-level cadence. Sources: create subscriptions , manage subscriptions , default line item properties .	Salesforce CPQ uses subscription terms, quote line effective dates, and Prorate Multiplier to calculate prorated prices and line totals. Salesforce Billing uses billing frequency and recurring order product dates for invoicing periods. Sources: Subscription Terms , CPQ quote date evaluation , Billing Frequency , Billing Dates .
Usage meter	A billing configuration that defines what usage should be measured for a usage-based product or rate plan, how raw usage events map to a customer/subscription item, and how those values are aggregated for an invoice period. A usage meter is not the same as a price: the meter produces the billable quantity, then the selected pricing model turns that quantity into money. Related concepts: meter event, usage event, usage quantity, aggregation method, customer mapping, value key, usage correction, and invoice-period usage summary.	Not implemented as a dedicated object. Current pricing supports usage-based /tier/package models and invoice simulation accepts <code>usageQuantities</code> per subscription item, but there is no meter definition table, event ingestion API, customer/event mapping, aggregation rule, correction workflow, or persisted usage summary yet. For Vexere, a future usage meter should likely attach to product/rate plan or subscription item version and feed <code>billing_invoice_lines.quantity</code> during payment-request generation.	Billing Meter / Meter Event for basic usage-based billing; Stripe now recommends Metronome for most new usage-based billing architecture. Meters define event name, aggregation, customer mapping, and value settings, then meter events are aggregated for billing. Sources: usage-based billing , create and configure a meter , record usage for billing .	Usage-based or metered billing is typically modeled through plans /addons and recurring usage charges. Closest Vexere mapping is a usage-based rate plan where usage quantity is captured before invoicing. Sources: plans overview , addons overview , create and manage subscriptions .	No dedicated usage meter object in standard subscription setup. Closest concept is a recurring line item with editable quantity/pricing model on a subscription; usage measurement would need to happen outside HubSpot and then update line-item quantity or invoice data. Source: create subscriptions .	Closest concepts are usage-based pricing / consumption schedules / usage records in Salesforce CPQ /Billing, where usage quantities are captured and rated for billing rather than modeled as a simple static subscription quantity. Sources: Subscription Products in Salesforce CPQ , Invoicing Recurring Products .
Billing event	A system or business event in the billing lifecycle. Billing is broader than collection: it covers calculation, billing period selection, invoice /payment-request generation, due dates, payment status, and collection follow-up. Collection actions are one family of billing events, not the whole meaning of billing. Current Vexere scope includes only four billing events: <code>collection_action_triggered</code> , <code>invoice_generated</code> , <code>invoice_overdue</code> , and <code>payment_received</code> .	Partially implemented through invoice simulation and invoice/payment state fields. No explicit billing event log or scheduler event model was found yet. Keep the current event vocabulary limited to <code>collection_action_triggered</code> , <code>invoice_generated</code> , <code>invoice_overdue</code> , and <code>payment_received</code> until the workflow expands.	Stripe exposes many event/webhook types around invoices, subscriptions, payments, payment intents, and collection attempts. Sources: Stripe events , webhooks .	Zoho has subscription, invoice, payment, credit note, and reminder lifecycle concepts rather than Vexere's explicit event vocabulary. Sources: subscriptions , invoices .	HubSpot exposes subscription and invoice/payment lifecycle concepts, including recurring billing setup and subscription management. Source: manage subscriptions .	Salesforce Billing has invoicing, payment, billing schedule, transaction, and adjustment lifecycle concepts. Sources: Billing Dates , Invoicing Recurring Products .
Collection timing	The business rule for when a collection operation is triggered for a phase. It does not mean billing equals collection action. In Vexere UI, the <code>Tháng</code> field answers: "When should the selected collection method be executed for this subscription phase or billing cycle?" Current options are <code>period_start / Ngày đầu kỳ</code> , <code>period_end / Cuối kỳ</code> , <code>cycle_day / Ngày trong kỳ</code> , and <code>before_period_start / Trước kỳ</code> . <code>cycle_day</code> means trigger on a specific day number inside the billing cycle, such as day 1, day 2, or day 15. <code>before_period_start</code> means trigger N days before the billing cycle starts, such as 5 days before the start of the period. The selected <code>collectionMethod</code> defines what action is executed, such as sending a payment request, offsetting ticket sales, or deducting from an operator wallet. Collection timing is phase-level, while item billing interval remains on the selected rate plan/price.	Partially implemented at subscription level only. DB uses <code>Subscriptions.collection_timing</code> with <code>period_start</code> , <code>period_end</code> , <code>cycle_day</code> , and <code>before_period_start</code> ; the API field is still <code>billingTiming</code> for frontend compatibility. UI captures a billing-cycle day or before-period-start offset and the API currently sends <code>billingAnchorDate</code> as the resolved date snapshot used for next bill/payment-request scheduling. Missing phase-level collection timing, production scheduler behavior, and invoice generation rules that use phase timing as source of truth.	Related to billing cycle anchor, invoice creation /finalization timing, and collection method behavior. Stripe exposes billing cycle anchor behavior and Subscription Schedule phase anchor behavior, but does not use Vexere's exact <code>collection timing</code> term. Sources: billing cycle , subscription schedules , Subscription Schedule object .	Related to billing date / next billing date and subscription renewal behavior. Zoho exposes billing frequency /date behavior rather than the exact Vexere timing terminology. Sources: create and manage subscriptions , subscription preferences .	Related to subscription billing date, next payment date, and payment schedule. HubSpot abstracts most anchor behavior behind subscription frequency and recurring billing setup. Source: create subscriptions .	Related to quote /contract effective dates, renewal terms, billing frequency, next billing date, invoicing process, and proration settings rather than a single timing concept. Sources: Billing Frequency , Billing Dates , CPQ quote date evaluation .
